

## Exercise 3.1

---

You can use exercise 2.1 from last week as a starting point.

The formula to convert a temperature given in Celsius to Fahrenheit is:

$$\text{Fahrenheit} = (9/5) * \text{Celsius} + 32$$

Write a program that asks the user to enter a temperature in Celsius. Your program should then convert it to Fahrenheit and displays the result in the form:

```
X Celsius is equivalent to Y Fahrenheit.
```

For example if the user inputted **20.2** the program output in the **console** will look like:

```
Please enter the temperature in Celsius:  
20.2  
20.2 Celsius is equivalent to 68.36 Fahrenheit.
```

- Your program should accept decimals such as **25.3**
- Your program should only calculate the result and display it if the user enters a value that is greater than or equal to zero.
- If the user enters a value that is less than **0**, the program should not display anything.

```
Please enter the temperature in Celsius:  
-1
```

***Note that to pass the tests you must have exactly the output above, apart from the numbers which will differ depending on what the user inputs.***
